

Take the different input from the user and print their datatypes.

```
# Taking different inputs from the user

name = input("Enter your name: ")
age = int(input("Enter your age: "))
salary = float(input("Enter your salary: "))
is_student = bool(input("Are you a student? (True/False): "))

# Printing values and their data types

print("Name:", name, "->", type(name))
print("Age:", age, "->", type(age))
print("Salary:", salary, "->", type(salary))
print("Is Student:", is_student, "->", type(is_student))
```

Sample Output:

```
Name: Rahul -> <class 'str'>
Age: 25 -> <class 'int'>
Salary: 50000.0 -> <class 'float'>
Is Student: True -> <class 'bool'>
```

Note: `input()` returns a string by default, so `int()`, `float()`, and `bool()` are used to convert the input into the required data types.
